## Abstract

Civil society participation in discussions about the transition of energy supply and demand structures is challenging due to limited access to technical and systemic knowledge. The asymmetry of knowledge between experts and non-experts can undermine the credibility of participatory processes. There are open-access-tools which are intended to improve the ability of stakeholders to engage in discussions as for example simulation-based tools that can provide insights into complex interactions. This paper summarises the results of our research about the question: To what extent do simulation-based tools empower stakeholders in participatory processes of the energy transition? This was done by a survey and categorization of existing tools followed by a qualitative evaluation of four cases and a concluding workshop where we discussed our resulting theses with experts from the different stakeholder groups. To define empowerment we drew on the participation pyramid by Rau et al. (2012) and Lüttringhaus (2003) consisting of four hierarchically sorted levels: Information, consultation, cooperation and delegation. The analyses showed 1) that tools can bring the discussion of a participatory process to a more objective level, 2) that to address user needs they must be involved in the programming process, and 3) that context variables influence the impact of a tool. Therefore, it is not only the tool itself that determines the outcome, but also the settings in which it is deployed. In this study we refer to simulation tools that reach at least the first steps of the participation pyramid as *stakeholder empowerment (StEmp) tools*. The full collection of added values of StEmp Tools, possible problems and requirements for future tools can be found in the flow chart, which has emerged from the workshop (see results).

*Keywords:* participation, empowerment tools, sustainable energy supply

## 1. Introduction

More than 80% of total greenhouse gas emissions in the EU are caused by the energy sector which makes the transition of the energy system one major challenge to climate change mitigation. Action planning and mitigation measures must consider interlaced systems such as political, economic, scientific and societal systems and the diverging interests of actors. The functioning and process organisation of different participation patterns to bring these actors together have been analysed in various research projects. However, research examining the mediation and organisation of the discourse between different stakeholders of the energy transition is scarce. [1], [2], [3]. Discussions about political, technical or juridical measures are often lead

by experts only because other stakeholders such as the civil society have limited access to technical and systemic knowledge. This asymmetry can undermine the credibility of participatory processes. There are tools which are intended to improve the ability of stakeholders to engage in discussions and contribute their specific knowledge. In this paper we will refer to them as *stakeholder empowerment (StEmp) tools*.

## 2. Objectives of the research

Tools based on simulations can provide insights into complex interactions (e.g. interrelationship between heat, electricity and mobility sector, climate influences, relevant players, etc.) and calculate impacts of specific measures. There are open

32 source tools with different degrees of complexity for  
33 modelling the energy system and processing energy  
34 data. To our knowledge, there are no studies to date  
35 that evaluate how such tools empower stakeholders  
36 to participate in trans-disciplinary dialogues con-  
37 cerning the transition of the energy system. This  
38 work addresses this gap in research. An additional  
39 aim of this paper is to identify the requirements for  
40 tools that can empower stakeholders as well as the  
41 limits and potential of their design.

### 42 3. Theoretical framework

43 The transformation of energy systems is very  
44 challenging as the need to change socio-technical  
45 systems implies the restructuring of deep-rooted so-  
46 cietal systems, the implementation of new technolo-  
47 gies and policy innovations. In this context differ-  
48 ent patterns of participation have been applied to  
49 either resolve energy conflicts, decrease opposition  
50 or to improve and secure the planning process. Par-  
51 ticipatory governance approaches on energy transi-  
52 tion describe the democratic participation through  
53 deliberative practices of citizens. Therefore, Borrás  
54 and Edler (2014: 28) [6] state: “The complex na-  
55 ture of socio-technical systems makes the partici-  
56 patory and effective governance of change in socio-  
57 technical systems more dependent on knowledge  
58 of citizens and experts alike.” In climate and en-  
59 ergy research, model-based studies have become the  
60 dominant form of knowledge production. Energy  
61 scenarios are based on energy models and certain  
62 assumptions of outcomes to assess future energy de-  
63 velopments (Karjalainen et al. 2014: 30)[7]. These  
64 model results and scenarios are of decisive impor-  
65 tance for scientific policy advice (Dieckhoff 2015: 14  
66 ff) [8]. However, the recipient (politician, adminis-  
67 tration, the economy and the civil society) needs  
68 profound model and systemic knowledge to under-  
69 stand the results and to be able to check the model  
70 towards its plausibility and validity.

71 We assume that simulation-based tools can be  
72 used to compensate the differences in knowledge  
73 and help to enable an equal discussion in which ev-  
74 ery participant can make a contribution. The tools  
75 consist of a user interface and an energy model as  
76 the mathematical framework. The parameters en-  
77 tered via the tool interface are simulated using the  
78 model which is implemented in the tool (as a soft-  
79 ware). The impacts of tools in participatory inte-  
80 grated assessments as well as participation in the

81 modelling process have been part of research ef-  
82 forts. Tuler et al. (2017: 25) [9] describe partici-  
83 patory modelling as a way of bringing stakehold-  
84 ers together to organize information about com-  
85 plex systems into tools that are more useful for  
86 local decision-making than those designed by sci-  
87 entists and decision makers alone.” These tools can  
88 be further used as instruments in participation pro-  
89 cesses. In result, tools are promising instruments,  
90 but summarizing the state of the art, they have  
91 often failed to fulfil all the expectations that were  
92 put into them (compare De Kraker et al. 2011 [10]  
93 and Siebenhühner/Barth 2004 [11]). That is why  
94 this paper concentrates on the ability of tools to  
95 empower Stakeholders in participatory processes.  
96 The empowerment perspective has not yet been  
97 covered by researchers, although it is essential to  
98 compensate asymmetries in knowledge and develop  
99 a proper understanding of the local energy system.  
100 Varying approaches and understandings of partici-  
101 pation have led to different typologisations in or-  
102 der to show the differences and similarities in their  
103 interpretation and conceptualisation of participa-  
104 tion (Reed 2008) [2]. In this context Arnsteins  
105 “ladder of participation” (1969) [12] is one of the  
106 most quoted approaches. It differentiates between  
107 participation and non-participation. According to  
108 Arnstein’s understanding, a sharing of power is nec-  
109 essary to truly enable participation of marginal-  
110 ized groups. Therefore, forms of information or  
111 consultation remain “degrees of Tokenism” (Arn-  
112 stein 1969) [12]. Lüttringhaus (2003) [5] and Rau  
113 et al. (2012) [4] have a similar approach, but in-  
114 stead of differentiating between participation and  
115 non-participation, they take up the ladder-model  
116 of Arnstein and attach to each stage or step a dif-  
117 ferent strong influence. In their definition, partici-  
118 pation starts already on the first step. They come  
119 up with a pyramid structured into five hierarchical  
120 steps that we also used for our evaluation: Informa-  
121 tion, consultation, cooperation, delegation and self-  
122 sufficiency. We further assume that the tools are  
123 the structuring instruments in the process to reach  
124 the steps. The information level includes, on the  
125 one hand, an explanation part of the functionality  
126 of the tool and, on the other hand, a thematic in-  
127 troduction supported by the tool. Consultation de-  
128 scribes the discussion in which the individual points  
129 of view can be depicted via the tool and thus the  
130 tool is the basis for the discourse. The coopera-  
131 tion stage stands for the joint scenario construc-  
132 tion through the tool. The stages of consultation

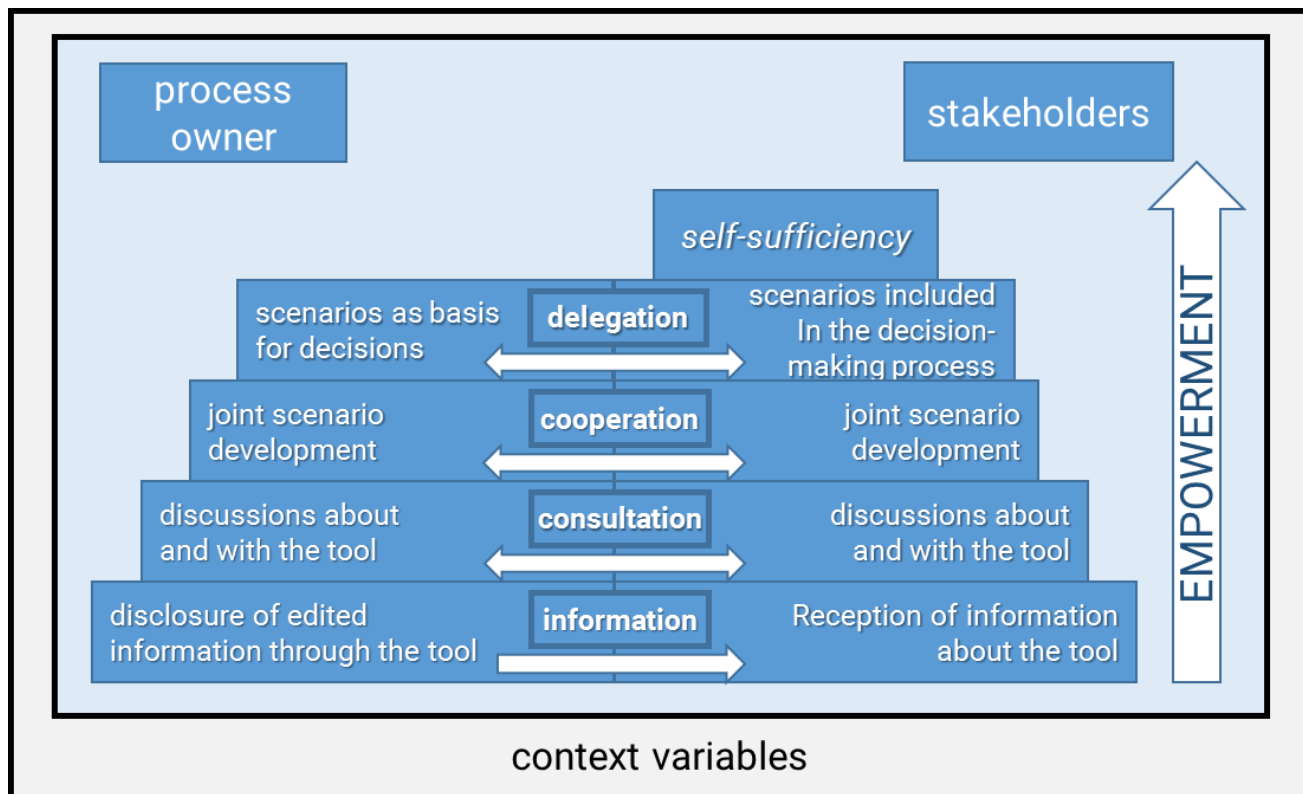

Figure 1: The five levels of stakeholder empowerment own depiction based on Rau et al.2012 [4] and Lüttringhaus 2003 [5]

133 and cooperation partly overlap, since the discussion  
 134 and the scenario construction are often interwoven  
 135 in the participation process. The level delegation  
 136 describes a shared responsibility which means that  
 137 the results will be considered in political decision-  
 138 making. The level of self-sufficiency is listed here as  
 139 an "ideal type", following Lüttringhaus (2003) and  
 140 Arnstein (1969).

141 In the paper of Späth and Scolobig (2016: 190) [3]  
 142 participation and empowerment have been linked:  
 143 *Participation and empowerment of stakeholders*  
 144 *start as soon as stakeholders are engaged in the*  
 145 *process.* Späth und Scolobig (2016: 190) argue fur-  
 146 *ther: The empowerment levels of stakeholders in a*  
 147 *process, although mostly not at the highest rungs as*  
 148 *described by Arnstein, can still be evaluated. There-*  
 149 *fore, an empowerment scale is appropriate to evalu-*  
 150 *ate the way stakeholders are embedded in a process.*  
 151 In accordance to Späth and Scolobig (2016) we also  
 152 link the degree of participation with the degree of  
 153 empowerment in this paper. Although stakehold-  
 154 ers from politics and administration already have  
 155 decision-making power we argue that they have to

156 be empowered to implement the energy transition  
 157 in their region. Therefore, they need the neces-  
 158 sary technical know-how, but also ensure the soci-  
 159 etal feasibility of the transition process (Alcántara  
 160 et al. 2016: 128 ff) [13].

#### 4. Methodology

162 Our analysis consists of three parts: We started  
 163 with a survey and categorization of existing  
 164 simulation-based online-tools followed by a qualita-  
 165 tive comparative case study. Finally, we conducted  
 166 a workshop to discuss our results and hypothe-  
 167 ses with experts from different stakeholder groups.  
 168 With the survey of online-tools we wanted to get  
 169 an extensive picture of the distribution and sub-  
 170 jects of the existing online-tools. This survey is not  
 171 representative. It is more about creating a compre-  
 172 hensive overview. Therefore, we researched tools  
 173 in English and German language. We only con-  
 174 sidered simulation-based open-access online tools,  
 175 which prepared energy related issues. We espe-  
 176 cially focused on the official online appearance of

177 the USA, Canada, Australia, Great Britain, the Eu- 227  
178 ropean Union, Germany, Austria and Switzerland. 228  
179 To analyse the impact of the tools in terms of the 229  
180 empowerment of stakeholders, we conducted an ex- 230  
181 ploratory comparative case study. In order to do 231  
182 so, we have chosen four cases. The cases had to 232  
183 fulfil the following criteria: 233

- 184 1. The tools have to be simulation-based and us- 234  
185 able to create energy scenarios 235
- 186 2. The tools have to be applied to support the re- 236  
187 gional implementation of the energy transition 237  
188 in Germany. 238
- 189 3. The tools must have been deployed more of- 239  
190 ten by the same person (workshop moderator) 240  
191 in different informal participatory contexts. In 241  
192 this way a better comparability of the similar- 242  
193 ities and differences and a better control of the 243  
194 context variables shall be ensured. 244

195 We decided for four cases complying with our crite- 245  
196 ria: *100prosim* is an excel-tool for yearly balanced 246  
197 calculations of the energy supply for any German 247  
198 region with the aim to reach 100% renewable en- 248  
199 ergy. The potential as well as the need of renew- 249  
200 able energy sources can be determined including the 250  
201 electricity-, heat- and transport sector. The con- 251  
202 sumption sectors household, commercial, industrial 252  
203 and transport are considered as well as the reduc-  
204 tion of energy demand. The users can build their  
205 own scenarios and discuss the different approaches.  
206 The tool was built proactively by one developer.

207 With the *Berlin heat calculator* it is possible  
208 to analyse the influences of the building refurb-  
209 ishments, energy sources and the heating type of  
210 Berlin (residential) buildings on the primary energy  
211 balance and the CO<sub>2</sub> balance. The potential of dif-  
212 ferent measures can be visualised through graphics.  
213 It can also determine the renovation costs of the  
214 (different) scenarios. It was commissioned by an  
215 NGO to support individual discussions with var-  
216 ious stakeholders about measures that should be  
217 included in upcoming policies.

218 The *Open-Source-Energy-Model Schleswig- 253  
219 Holstein* (OpenMod.sh) was developed for the 254  
220 region of Kiel to support public workshops to 255  
221 develop a Masterplan for climate protection. It is 256  
222 an optimizing tool calculating in time steps of one 257  
223 hour and providing the possibility to include heat, 258  
224 electricity and gas. 259

225 *Erneuerbar Komm* is a tool that provides the re- 260  
226 gional potential of the energy sources wind, PV, 261

227 water and biomass. It reflects the relationship be- 228  
229 tween generated electricity and the required area. 230  
231 It is an easy to handle online tool that answers the 232  
233 question: which percentage of the regional electric- 234  
235 ity demand of private households can be covered 236  
237 by sun, wind, biomass and water from the region? 238  
239 The last two tools have been developed as part of 240  
241 ongoing projects. 242

243 To evaluate the degree of empowerment of the 244  
245 participating stakeholders, we conducted seven 246  
247 guided interviews with the developers of the tools 248  
249 and with the moderators who lead different work- 250  
251 shops with the tools and additional with one com- 252  
253 munication expert who conducted many partici-  
254 patory processes concerning regional energy ques-  
255 tions. The interviews took about an hour and have  
256 been recorded. The evaluation was made via the  
257 participation pyramid (see 1. As this is an ex-  
258 ploratory study, we derived 5 hypotheses from the  
259 analysis and developed the concept of Stakeholder  
260 Empowerment Tools (StEmp Tool). 261

262 The hypotheses and requirements concerning the 263  
264 development of future StEmp Tools were discussed 265  
266 in a concluding workshop with 15 stakeholders from 267  
268 different backgrounds (amongst others developers 269  
270 and users as well as prospective users). 271

## 253 5. Results

254 **Results from the tool-survey:** We gathered 255  
256 more than 130 tools and clustered them accord- 257  
258 ing to their type and their main subject. The 259  
260 6 type clusters were web-tools, visualisation-tools, 261  
262 mapping-tools, excel-tools, games and software. 263  
264 The content related categories to which the tools 265  
266 were assigned were energy systems, electricity, heat, 267  
268 mobility, grids, efficiency, climate adaption, climate 269  
270 mitigation, economic feasibility and policies. 31 of 271  
272 the analysed tools address energy systems and 57 of  
273 them are web-tools. Figure 2 gives an overview of  
274 the thematic categories the tools belong to as well  
275 as on the share the various types of tools have.

276 The following two hypotheses include a summary 277  
278 of the observed connections from the tool review. 279  
280 These are supposed to be considered more as a ten- 281  
282 dency than as causal connection. They serve as 283  
284 indication for further research. 285

- 286 • The more specific the tools treat a certain 287  
288 topic, the more difficult becomes the access for 289  
290 non-specialist users, which could restrict the 291  
292 empowerment effect. 293

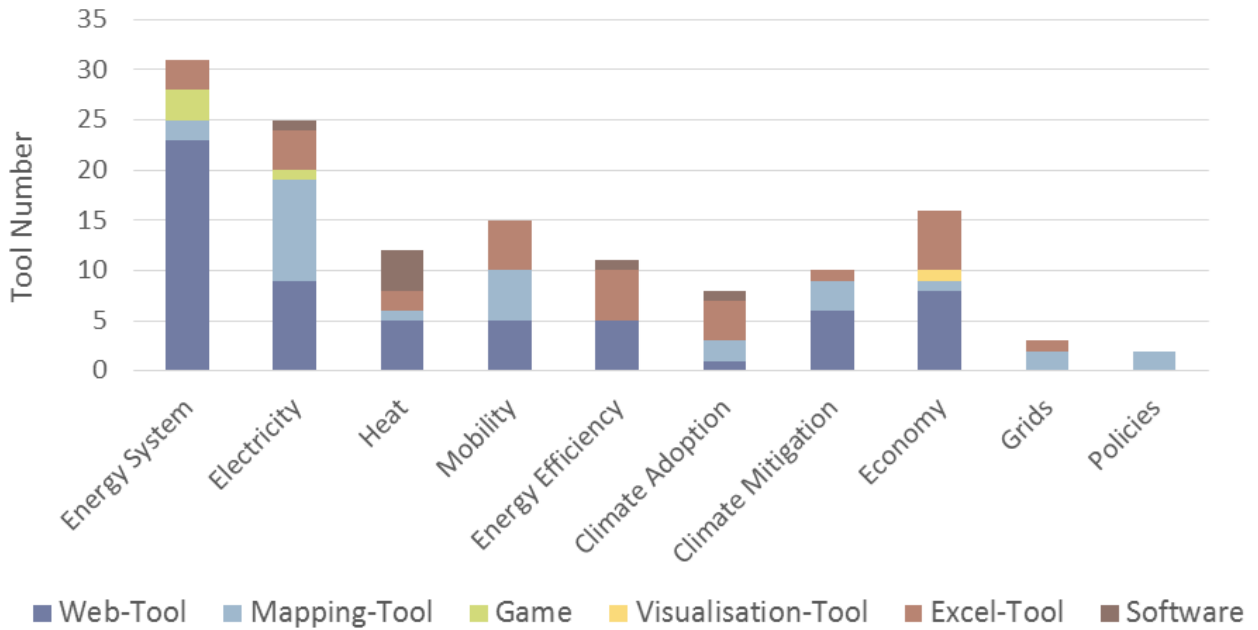

Figure 2: Analysis of the tool landscape

- The more flexible one can adjust the parameters, the more special knowledge is necessary to use the tool, which could restrict the empowerment effect.

The survey is the starting point for the subsequent comparative case study which was necessary to work on questions regarding the impact since the effect of empowerment is hard to evaluate for pure online tools.

**Results from the qualitative case study:** Regarding our research question the degree of empowerment depends not only on the tool itself, but also on the process design. This has to meet the basic requirements for participation processes design as described by Webler and Renn [14] (e.g. time management, process organization, etc.) and the context variables (the values of the participants, the specific socio-economic factors of the region, etc.). They varied in the evaluated cases and are hard to control. Thus, context variables are the limiting factors of this study. We summarize the results of the four case studies regarding the most important points of the development phase of the tools and the degree of empowerment in relation to the levels of the participation pyramid and the future perspectives of tools in participation processes.

An important finding of the development phase is that there has been a close cooperation between the developer side and the user side (workshop moderator). This is necessary to bridge the technical aspects with questions of practicability for the participatory process. However, this has led to conflicting objectives in the development phase as the developers were emphasizing the importance of depicting the complexity of the energy system whereas the user side focused more on reducing the interface on the functions that can be used and mediated in a participatory process. Working on this conflict together was reported to be helpful for both sides. The users learned about the interaction of modelling and user interface and the modellers reflected their work in terms of the ease of use. Furthermore, in two cases (Erneuerbar Komm and the Berlin Heat Calculation Tool) the definition of the assumptions during the development phase has been participatory. According to the interviewee this has led to a higher acceptance of the tool and an understanding of its technical functioning.

Concerning the implementation of tools in various participatory processes interviewees reported that stakeholder tools helped them to better understand the field and to feel comfortable partici-

328 participating in discussions with subject-matter experts.  
329 By reconciling the case studies with the participa-  
330 tion pyramid, we identified high levels empower-  
331 ment. In all cases the level *information* has been  
332 reached. We considered the levels *consultation* and  
333 *cooperation* together since they partly overlap. The  
334 complexity of the tool in relation to the level of  
335 prior knowledge of the participating stakeholders  
336 and the time frame in which the necessary knowl-  
337 edge could be conveyed to the them was critical for  
338 either reaching these steps or not. Therefore, in-  
339 tegrating all stakeholders in the scenario construc-  
340 tion was not possible in all cases due to the high  
341 complexity of one tool (OpenMod.sh). In the con-  
342 text of these two levels the impact of the tools on  
343 the discourse is another important aspect. Accord-  
344 ing to the interviewees a strength of the tools is  
345 that they can structure discussions and make them  
346 more concrete because the participants have to de-  
347 cide upon concrete Input parameters. Due to focus-  
348 ing on facts, e.g. geographic conditions, technical  
349 aspects and measures resulting from joint calcula-  
350 tions, emotions can be percolated. Achieving the  
351 level of *delegation* depends on the process not on  
352 the tool. Even though there are differences between  
353 the analysed tools nearly all of them were used to  
354 create regional climate protection concepts. Espe-  
355 cially for this relatively open process with specified  
356 objectives, this kind of simulation tools proved to  
357 be useful. Therefore, we concluded that high levels  
358 of participation and thus of empowerment can be  
359 achieved through tools.

360 Concerning the online availability of the tools the  
361 assessment of the interviewees varied significantly.  
362 While half of them stressed the point that an ap-  
363 plication without energy system and model knowl-  
364 edge can lead to misinterpretations unless the tool  
365 interface is so restrictive that the users can hardly  
366 configure the system according to their needs, the  
367 others rather stated that low-threshold online tools  
368 will be very useful to gain more common under-  
369 standing of the energy subject.

370 The following hypotheses derived from our work:

371 H1: The more the process design and the  
372 discussions are oriented on the design and the  
373 functionalities of the tool, the higher is the degree  
374 of empowerment of the involved stakeholders.

375  
376 H2: If the development process of the tool was  
377 participatory the acceptance of the tool enhances  
378 and then the degree of empowerment of the involved  
379 stakeholders increases.

380 H3: The higher the acceptance of the tool  
381 as a valid and effective instrument, the higher  
382 is the degree of empowerment of the involved  
383 stakeholders.

384  
385 H4: The better the tool can balance the different  
386 knowledge levels of the stakeholders, the higher  
387 is the degree of empowerment of the involved  
388 stakeholders.

389  
390 H5: If the context variables enable an open  
391 discussion with politically relevant results as well  
392 as an individual process design that takes the  
393 specific regional socio-structural conditions into  
394 account, then the degree of empowerment of the  
395 involved stakeholders increases.

396  
397 **Conceptualization of Stakeholder Empow-**  
398 **erment Tools (StEmp tool)** The analyzed four  
399 tools have not been developed with the aim of em-  
400 powering the participants. Therefore, the concept  
401 of StEmp tool is intended to be the basis for future  
402 tool developments aiming to increase the ability of  
403 stakeholders to participate in complex issues. Ad-  
404 ditionally, this concept shall help to overcome the  
405 shortcomings identified in the application of tools.  
406 Consequently, StEmp tools have to be simulation-  
407 based as the application of these tools is in the  
408 area of model-based decisions-making. Moreover,  
409 a regional orientation of the tool does help to es-  
410 tablish a direct relation to the local stakeholders.  
411 The need of political, societal and economic stake-  
412 holders for empowerment is the need of prepared  
413 knowledge, local data, transparency and communi-  
414 cation with each other. Therefore, a StEmp tool  
415 has to be based on concrete regional requirements.  
416 The transparency of the tool requires conceptually  
417 two things: Firstly, the tools have to be developed  
418 based on open source software and licenses to guar-  
419 antee a free online use. The goal is to open up  
420 new information channels. The online availability,  
421 however, must be accompanied by comprehensive  
422 user guides, especially when it comes to complex  
423 tools. Secondly, the stakeholders must also be in-  
424 cluded in the definition of the underlying assump-  
425 tions. In two cases this procedure has proven to be  
426 helpful. It has increased the acceptance of the tool  
427 and ensured that the tool deals with the relevant  
428 questions for the stakeholders. Another aspect of  
429 StEmp tools is that they are used in participation  
430 processes and thus have a clear, practical orienta-  
431 tion. Since the degree of participation corresponds

432 to the understanding of empowerment in this work,  
433 this is also transferred to the StEmp tool concept:  
434 The Participation processes in which tools are used  
435 have to have a clear empowerment aim and there-  
436 fore enhance the discourse and dismantle knowledge  
437 asymmetries.

438 **Results from the workshop:** The evaluation  
439 was concluded with the workshop to discuss and  
440 concretise all findings with a larger group of ex-  
441 perts. There was a broad consensus about the re-  
442 sults especially that the interactions of process de-  
443 sign and tool requires further research. The discus-  
444 sion focused on added values of StEmp Tools, pos-  
445 sible problems and requirements for future tools.  
446 Subsequently we developed a flow chart (see figure  
447 3) covering the workshop results.

## 448 6. Conclusions

449 This paper is an empirical study consisting of two  
450 parts to investigate the research question. First we  
451 surveyed the existing online-tools and then a com-  
452 parative case study with four cases was carried out.  
453 Through the comparative case study, we have ex-  
454 plored five hypotheses, which illustrate the relation-  
455 ship between tool application in participatory pro-  
456 cesses and the empowerment of the participating  
457 stakeholders. Tools are no new formats of partic-  
458 ipation they remain an instruments that can en-  
459 hance the participation process. In the process, the  
460 tool provides the framework for the technical feasi-  
461 bility and the stakeholders provide the input con-  
462 cerning the social practicability. In result tools as  
463 instruments in participatory processes have a great  
464 potential for empowerment, which has been proven  
465 in the four cases. However, this potential can only  
466 be realized in relation to the process design and  
467 the context variables. In addition, the workshop  
468 leader has an intermediary role and mediates be-  
469 tween development and application, and thus tech-  
470 nical design and practical use, thereby he can act  
471 as multiplier.

472 Tools as instruments in processes of participa-  
473 tory climate change governance at the local level  
474 help to increase the transparency of the energy is-  
475 sue. Furthermore, the tool as the basis of discus-  
476 sion can improve the communication between the  
477 participants because also participants without prior  
478 expert knowledge in energy subjects can contribute  
479 their views into the discussion. The complex co-  
480 herencies of the local energy system are prepared

481 and mediated through the tool, whereby new im-  
482 pressions, perspectives and new knowledge can be  
483 gained by the stakeholders. In this way politicians  
484 as well as for example actors of the civil society  
485 gain new insights and can jointly decide about the  
486 scenario construction and therefore about the im-  
487 plementation of the energy transition. This cor-  
488 responds with the political value of the tool ap-  
489 plication. Tools open up the blackbox of energy  
490 modelling which improves the political connectiv-  
491 ity of the scenarios and workshop results. However,  
492 to ensure the political implementation, the level of  
493 "delegation" must be achieved in the participatory  
494 process. In two of the four analysed cases this have  
495 been achieved.

496 The process design has to be precisely tailored to  
497 the tool and the other way around the tool devel-  
498 opment has to consider the application of the tool  
499 in participatory processes. However, the limiting  
500 factors of the tools remain the context variables.  
501 Therefore, further research needs to be done to val-  
502 idate the hypotheses of this study and to analyse  
503 further application of tools. Additionally, we have  
504 not covered the usage of tools in energy conflicts.  
505 In emotionalised contexts it is very questionable  
506 whether instruments that aim to bring new knowl-  
507 edge and perspectives into the group are accepted  
508 at all.

## 509 Acknowledgement

510 The authors thank the *German Federal Ministry for*  
511 *Education and Research* for funding the research project  
512 *ENavi* as part of the Kopernikus projects.
